

LINEAR REGRESSION

Linear regression models assume a linear relationship between the inputs X_1, X_2, \dots, X_p and the output Y . These models are simple and often provide an insight into the effect of input variables on the output variable. Linear models can be expanded to transformations of the input variables, thus making them widely applicable.

1 Single Variable Regression

Given training data of the form $(x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)$; the idea is to come up with the best estimate \hat{y} such that,

$$\hat{y} = \beta_0 + \beta_1 x$$

This scheme makes an estimation error at each point,

$$\begin{aligned}\epsilon_i &= y_i - \hat{y}_i \\ &= y_i - (\beta_0 + \beta_1 x)\end{aligned}$$

Generally, sum of squares of all the N errors is minimized to define the best fit. Thus, the objective is to choose β_0 and β_1 such that this Residual Square Sum (RSS) is as small as possible. The errors are visualized below,

Note that as line moves away from the data points the RSS gets bigger since each error becomes bigger. In fact there is no upper bound on RSS , only a lower bound. Hence to get the minimum RSS , equating partial differentials w.r.t. β_0 and β_1 to zero is sufficient without worrying if the extrema is maxima or minima, it is always guaranteed to be a minima.

$$RSS(\beta_0, \beta_1) = \sum_{i=1}^N (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\frac{\partial RSS}{\partial \beta_0} = -2 \sum_{i=1}^N (y_i - \beta_0 - \beta_1 x_i)$$

$$\frac{\partial RSS}{\partial \beta_1} = -2 \sum_{i=1}^N (y_i - \beta_0 - \beta_1 x_i) x_i$$

Equating both to zero,

$$\beta_0 N + \beta_1 \sum x_i = \sum y_i$$

$$\beta_0 \sum x_i + \beta_1 \sum x_i^2 = \sum x_i y_i$$

This can be written in matrix form as follows,

$$\begin{pmatrix} N & \sum x_i \\ \sum x_i & \sum x_i^2 \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \end{pmatrix} = \begin{pmatrix} \sum y_i \\ \sum x_i y_i \end{pmatrix}$$

Multiplying by inverse of the 2×2 matrix on both sides,

$$\begin{pmatrix} \beta_0 \\ \beta_1 \end{pmatrix} = \begin{pmatrix} N & \sum x_i \\ \sum x_i & \sum x_i^2 \end{pmatrix}^{-1} \begin{pmatrix} \sum y_i \\ \sum x_i y_i \end{pmatrix}$$

$$= \frac{1}{N \sum x_i^2 - (\sum x_i)^2} \begin{pmatrix} \sum x_i^2 & -\sum x_i \\ -\sum x_i & N \end{pmatrix} \begin{pmatrix} \sum y_i \\ \sum x_i y_i \end{pmatrix}$$

$$= \frac{1}{N \sum x_i^2 - (\sum x_i)^2} \begin{pmatrix} \sum x_i^2 \sum y_i - \sum x_i y_i \sum x_i \\ N \sum x_i y_i - \sum x_i \sum y_i \end{pmatrix}$$

Dividing both numerator and denominator by N^2 , β_0 and β_1 can be represented in terms of averages as follows,

$$\beta_0 = \frac{Avg(x^2)Avg(y) - Avg(xy)Avg(x)}{Avg(x^2) - [Avg(x)]^2}$$

$$\beta_1 = \frac{Avg(xy) - Avg(x)Avg(y)}{Avg(x^2) - [Avg(x)]^2} = \frac{Cov(x, y)}{Var(x)}$$

After the calculation of β_0 and β_1 , the goodness of fit is measured by correlation,

$$r = \frac{Cov(x, y)}{\sqrt{Var(x)Var(y)}}$$

Correlation always resides in the interval $[-1, 1]$. It is 1 or -1 if all the data points (x_i, y_i) lie on a line.

1.1 Input Transformations

- Relationship between x and y is not linear if $y = x^n$. Taking \log on both sides, $\log(y) = n\log(x)$. Clearly relationship between $\log(x)$ and $\log(y)$ is linear.
- Relationship between x and y is not linear if $y = a^x$. Taking \log on both sides, $\log(y) = x\log(a)$. Clearly, relationship between $\log(y)$ and x is linear.
- Due to scenarios like this, the inputs are sometimes transformed appropriately before being fed into a linear regression model.

2 Multiple Variable Regression

In the general case, the equation becomes

$$\hat{y} = \beta_0 + \sum_{j=1}^p \beta_j x_j$$

Let \mathbf{X} be $N \times (p + 1)$ matrix where the first column is all ones and the j^{th} column represents the N values of the input variable x_j . Similarly, let \mathbf{Y} be a vector of the N values of the output variable y . For all the N given observations, it can be written,

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta}$$

The error vector becomes,

$$\epsilon = \mathbf{y} - \mathbf{X}\beta$$

The residual sum of squares can be represented as,

$$\begin{aligned} RSS(\beta) &= \epsilon^T \epsilon \\ &= (\mathbf{y} - \mathbf{X}\beta)^T (\mathbf{y} - \mathbf{X}\beta) \\ &= (\mathbf{y}^T - \beta^T \mathbf{X}^T) (\mathbf{y} - \mathbf{X}\beta) \\ &= \mathbf{y}^T \mathbf{y} - \beta^T \mathbf{X}^T \mathbf{y} - \mathbf{y}^T \mathbf{X} \beta + \beta^T \mathbf{X}^T \mathbf{X} \beta \end{aligned}$$

Taking the derivative w.r.t. β

$$\begin{aligned} \frac{\partial RSS(\beta)}{\partial \beta} &= \frac{\partial}{\partial \beta} (\mathbf{y}^T \mathbf{y}) - \frac{\partial}{\partial \beta} (\beta^T \mathbf{X}^T \mathbf{y}) - \frac{\partial}{\partial \beta} (\mathbf{y}^T \mathbf{X} \beta) + \frac{\partial}{\partial \beta} (\beta^T \mathbf{X}^T \mathbf{X} \beta) \\ &= 0 - \mathbf{X}^T \mathbf{y} - \mathbf{X}^T \mathbf{y} + 2\mathbf{X}^T \mathbf{X} \beta \\ &= -2\mathbf{X}^T \mathbf{y} + 2\mathbf{X}^T \mathbf{X} \beta \end{aligned}$$

Equating the derivative to zero for minimization,

$$\begin{aligned} \mathbf{X}^T \mathbf{X} \hat{\beta} &= \mathbf{X}^T \mathbf{y} \\ \hat{\beta} &= (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y} \end{aligned}$$

3 Gauss-Markov Theorem
